

# Metamodels and the valuation of large variable annuity portfolios

Guojun Gan, PhD, FSA Emiliano A. Valdez, PhD, FSA University of Connecticut

First Annual UCSB InsurTech Summit University of California, Santa Barbara Friday, May 3, 2019

### Efficient valuation of large variable annuity portfolios

#### **Running Time**

3. Numerical results

### What is a variable annuity?

A variable annuity is a retirement product, offered by an insurance company, that gives you the option to select from a variety of investment funds and then pays you retirement income, the amount of which will depend on the investment performance of funds you choose.

#### Variable annuities come with guarantees

UCSB InsurTech Summit 2019

### Insurance companies have to make guarantee payments under bad market conditions

Example (An immediate variable annuity with GMWB)

- Total investment and initial benefits base: \$100,000
- Maximum annual withdrawal: \$8,000

Policy Year	INV Return	Fund Before WD	Annual WD	Fund After WD	Remaining Benefit	Guarantee CF
1	-10%	90,000	8,000	82,000	92,000	0
2	10%	90,200	8,000	82,200	84,000	0
3	-30%	57,540	8,000	49,540	76,000	0
4	-30%	34,678	8,000	26,678	68,000	0
5	-10%	24,010	8,000	16,010	60,000	0
6	-10%	14,409	8,000	6,409	52,000	0
7	10%	7,050	8,000	0	44,000	950
8	r	0	8,000	0	36,000	8,000
:	÷	:	:	:	:	÷
12	r	0	8,000	0	4,000	8,000
13	r	0	4,000	0	0	4,000

Gan/Valdez (U. of Connecticut)

UCSB InsurTech Summit 2019

### Dynamic hedging

Dynamic hedging is a popular approach to mitigate the financial risk, but

- Dynamic hedging requires calculating the dollar Deltas of a portfolio of variable annuity policies within a short time interval.
- The value of the guarantees cannot be determined by closed-form formula.
- The Monte Carlo simulation model is time-consuming.

There is also the additional computational issue related to reflect the effect of dynamic hedging in (quarterly) financial reporting.

#### Use of Monte Carlo method

Using the Monte Carlo method to value large variable annuity portfolios is time-consuming:

Example (Valuing a portfolio of 100,000 policies)

- 1,000 risk neutral scenarios
- 360 monthly time steps

 $100,000 \times 1,000 \times 360 = 3.6 \times 10^{10}!$ 

 $\frac{3.6\times10^{10} \text{ projections}}{200,000 \text{ projections/second}} = 50 \text{ hours!}$ 

Gan/Valdez (U. of Connecticut)

UCONN, 7 / 31

## Metamodeling

- A metamodel, also a surrogate model, is a model of another model.
- Metamodeling has been applied to address the computational problems arising from valuation of variable annuity portfolios: a number of work published by co-author G. Gan.
- It involves four steps:

### Selecting representative policies

An important step in the metamodeling process is the selection of representative policies. Gan and Valdez (2016) compared five different experimental design methods for the GB2 regression model:

- Random sampling
- Low-discrepancy sequence
- Data clustering (hierarchical k-means)
- Latin hypercube sampling
- Conditional Latin hypercube sampling

9 / 31

### Some metamodels proposed/examined

We have studied and proposed some metamodels for the valuation of large VA portfolios:

- Ordinary kriging
- Universal kriging
- GB2 regression model
- Rank-order kriging (quantile kriging)
- Tree-based models joint work with Z. Quan

Kriging has its origins in geostatistics or spatial analysis. It is in some sense an interpolation method that is closely related to the idea of regression.

## A portfolio of synthetic variable annuity policies

Feature	Value
Policyholder birth date	[1/1/1950, 1/1/1980]
Issue date	[1/1/2000, 1/1/2014]
Valuation date	1/1/2014
Maturity	[15, 30] years
Account value	[50000, 500000]
Female percent	40%
Product type	DBRP, DBRU, BBSU, etc.
Fund fee	30, 50, 60, 80, 10, 38, 45, 55, 57, 46bps
	for Funds 1 to 10, respectively
Base fee	200 bps
Rider fee	depends on product type
Number of funds invested	[1, 10]

#### VA product types in the synthetic portfolio

#### Tree-based models

Quan, Gan and Valdez (2019) compared the prediction performance of various tree-based models:

- Classification and Regression Trees (CART)
  - pruned by introducing penalty
- Ensemble methods: aggregate several regression trees to improve prediction accuracy
  - Bagging and random forests
  - Gradient boosting
- Unbiased recursive partitioning:
  - Conditional inference trees
  - Conditional random forests

16 / 31

#### Unbiased recursive partitioning

CART algorithms employ what is called recursive binary partitioning, which uses greedy search causing some drawbacks:

- Overfitting
  - Use a pruning process by applying cross-validation
- Bias in variable selection
  - Especially true when the explanatory variables present many possible splits or have missing values
  - Hothorn, et al. (2006) introduced conditional inference trees based on a partitioning of a statistic that is used to measure the association between the response and the explanatory variables.

### Concluding remarks

We explore tree-based models and their extensions in developing metamodels for predicting fair market values. Besides computational efficiency and predictive accuracy, they have several advantages as an alternative predictive tool:

- Tree-based models are considered as nonparametric models that do not require distribution assumptions.
- Tree-based models can perform variable selection by assessing the relative importance.
- Tree-based models, especially with single smaller-sized trees, are straightforward to interpret by a visualization of the tree structure. This visualization was illustrated both in the case of regression tree and conditional inference tree.
- When compared to other metamodels for prediction purposes, tree-based models require less data preparation as they preserve the original scale to be more interpretable.

### Metamodeling book

#### Metamodeling for Variable Annuities

Variable annuties are life insurance products that offer various types of financial guarantees. Especially for insurers with large variable annulty portfolos, valuation of these guarantees is computationally intensive. Metamodeling for Variable Annutibes is devold to metamodeling approaches that have been proposed recently in the academic iterature to address the computational problems.

This book is primarily written for undergraduate students, who study acturalis dence statistics, risk managemen, and financial mathematics. It is equaly useful for practitioners, who work in insurance comparies, consulting firms, and barks. The book is also a source of herence for researchers and graduate students with scholarly inferent in computational issues related to variable annultes and other similar insurance products.

- Key features of this book include:
- Three experimental design methods and six metamodels are covered in detail
- · Theories behind the methods are clearly presented
- Methods are comprehensively demonstrated by a synthetic dataset
- Data and R source code are publicly accessible
- Numerical results are easily reproducible

#### Appendix: Validation measures

Validation measure	Description	Interpretation
Gini Index	$Gini = 1 - \frac{2}{N-1} \left( N - \frac{\sum_{i=1}^{N} i\tilde{y}_i}{\sum_{i=1}^{N} \tilde{y}_i} \right)$	Higher Gini is better.
	where $\tilde{y}$ is the corresponding to $y$ after ranking the corresponding predicted values $\widehat{y}.$	
Coefficient of Determination	$R^{2} = 1 - \frac{\sum_{i=1}^{N} (\widehat{y}_{i} - y_{i})^{2}}{\sum_{i=1}^{N} \left(y_{i} - \frac{1}{n} \sum_{i=1}^{n} y_{i}\right)^{2}}$	Higher $R^2$ is better.
	where $\widehat{y}$ is predicted values.	
Concordance Correlation	$CCC = \frac{2\rho\sigma_{\widehat{y}_i}\sigma_{y_i}}{\sigma_{\widehat{y}_i}^2 + \sigma_{y_i}^2 + (\mu_{\widehat{y}_i} - \mu_{y_i})^2}$	Higher CCC is better.
Coefficient	where $\mu_{\widehat{y}_i}$ and $\mu_{y_i}$ are the means	
	$\sigma_{\widehat{y}_i}^2$ and $\sigma_{y_i}^2$ are the variances $ ho$ is the correlation coefficient	
Mean Error	$ME = \frac{1}{N} \sum_{i=1}^{N} (\hat{y}_i - y_i)$	Lower $\left  ME \right $ is better.
Percentage Error	$PE = \frac{\sum_{i=1}^{N} \hat{y}_i - \sum_{i=1}^{N} y_i}{\sum_{i=1}^{N} y_i}$	Lower $\left  PE \right $ is better.
Mean Squared Error	$MSE = \frac{1}{N} \sum_{i=1}^{N} (\widehat{y}_i - y_i)^2$	Lower $MSE$ is better
Mean Absolute Error	$MAE = \frac{1}{N} \sum_{i=1}^{N}  \widehat{y}_i - y_i $	Lower MAE is better.

### Appendix: Tuning hyperparameters

R package	Description
rpart	Classification and regression tree (CART)
cp minsplit maxdepth	complexity parameter minimum number of observations in a node in order to be considered for splitting maximum depth of any node of the final tree
randomForest	Bagging and Random Forests
mtry	number of explanatory variables randomly sampled as candidates at each split
nodesize ntree	minimum number of observations in the terminal nodes number of trees to grow/bootstrap samples
gbm	Gradient boosting
n.trees	number of trees to fit/iterations/basis functions in the additive expansion maximum denth of variable interactions(1 implies an additive model
n.minobsinnode shrinkage	2 means a model with up to 2-way interactions) minimum number of observations in the terminal nodes shrinkage parameter(learning rate or step-size reduction)
party/partykit	Conditional inference trees
teststat splitstat testtype alpha minsplit	type of the test statistic to be applied for variable selection type of the test statistic to be applied for split point selection the way to compute the distribution of the test statistic significance level for variable selection minimum sum of weights in a node in order to be considered for splitting
party/partykit	Conditional random forests
mtry	number of explanatory variables randomly sampled as candidates at each split
ntree	number of trees to grow/bootstrap samples
